Thermodynamic formulation

Developed models are completely defined by two potential functions: the **specific Helmholtz free energy** $\psi = \psi(T, \varepsilon_{te}, \omega)$, (linear kinematics assumed $\varepsilon = \varepsilon_e + \varepsilon_c + \varepsilon_{th}$, $\varepsilon_{te} = \varepsilon - \varepsilon_c$, $\omega = 1 - D$) and the **complementary dissipation potential** $\varphi(Y, q, \sigma; T, \omega)$ defined as

$$\gamma = \frac{\partial \varphi}{\partial q} \cdot q + \frac{\partial \varphi}{\partial \sigma} \cdot \sigma + \frac{\partial \varphi}{\partial Y} Y.$$

Together with the Clausius-Duhem inequality

$$\gamma = -\rho(\dot{\psi} + s\dot{T}) + \boldsymbol{\sigma} : \dot{\boldsymbol{\varepsilon}} - T^{-1} \operatorname{grad} T \cdot \boldsymbol{q} \ge 0$$

results the constitutive equations

$$-\rho\left(s+\frac{\partial\psi}{\partial T}\right)\dot{T} + \left(\boldsymbol{\sigma}-\rho\frac{\partial\psi}{\partial\boldsymbol{\varepsilon}_{\text{te}}}\right):\dot{\boldsymbol{\varepsilon}}_{\text{te}} + \left(\dot{\boldsymbol{\varepsilon}}_{c}-\frac{\partial\varphi}{\partial\boldsymbol{\sigma}}\right):\boldsymbol{\sigma} \\ -\left(\dot{\boldsymbol{\omega}}+\frac{\partial\varphi}{\partial Y}\right)Y - \left(\frac{\text{grad}T}{T}+\frac{\partial\varphi}{\partial\boldsymbol{q}}\right)\cdot\boldsymbol{q} = 0.$$

Specific models

The specific Helmholtz free energy

$$\rho \psi = \rho c_{\varepsilon} \left(T - T \ln \frac{T}{T_{\rm r}} \right) + \frac{1}{2} (\boldsymbol{\varepsilon}_{\rm te} - \boldsymbol{\varepsilon}_{\rm th}) : \boldsymbol{\omega} \boldsymbol{C}_{\rm e} : (\boldsymbol{\varepsilon}_{\rm te} - \boldsymbol{\varepsilon}_{\rm th}),$$

 $\varepsilon_{\rm th} = \alpha (T - T_{\rm r})$, thermal strain, $C_{\rm e}$ elasticity tensor, α thermal expansion coefficients, $T_{\rm r}$ stress free reference temperature.

The complementary dissipation potential

$$\varphi(Y, \boldsymbol{q}, \boldsymbol{\sigma}; T, \omega) = \varphi_{\mathrm{th}}(\boldsymbol{q}; T) + \varphi_{\mathrm{d}}(Y; T, \omega) + \varphi_{\mathrm{c}}(\boldsymbol{\sigma}; T, \omega),$$

where the thermal part is

$$\varphi_{\mathrm{th}}(\boldsymbol{q};T) = \frac{1}{2}T^{-1}\boldsymbol{q}\cdot\boldsymbol{\lambda}^{-1}\boldsymbol{q}.$$

For creep the following Norton type potential function is adopted

$$\varphi_{\rm c}(\boldsymbol{\sigma};T,\omega) = \frac{h_{\rm c}(T)}{p+1} \frac{\omega \sigma_{\rm rc}}{t_{\rm c}} \left(\frac{\bar{\sigma}}{\omega \sigma_{\rm rc}}\right)^{p+1}$$

 $\bar{\sigma} = \sqrt{3J_2}$, $h_{\rm c}(T) = \exp(-Q_{\rm c}/RT)$.

Damage potential

Kachanov-Rabotnov type

$$\begin{aligned} \varphi_{\mathrm{d}}(Y;T,\omega) &= \frac{h_{\mathrm{d}}(T)}{r+1} \frac{Y_{\mathrm{r}}}{t_{\mathrm{d}}\,\omega^{k}} \left(\frac{Y}{Y_{\mathrm{r}}}\right)^{r+1}, \quad \mathrm{model} \ 1\\ \varphi_{\mathrm{d}}(Y;T,\omega) &= \frac{h_{\mathrm{c}}(T)}{\left(\frac{1}{2}p+1\right)\left(1+k+p\right)} \frac{Y_{\mathrm{r}}}{t_{\mathrm{d}}\,\omega^{k}} \left(\frac{Y}{Y_{\mathrm{r}}}\right)^{\frac{1}{2}p+1}, \mathrm{model} \ 2\end{aligned}$$

 $t_{\rm d}$ is a characteristic time for damage evolution, $h_{\rm d}(T)=\exp(-Q_{\rm d}/RT)$, where $Q_{\rm d}$ is the damage activation energy and R is the universal gas constant. The reference value $Y_{\rm r}=\sigma_{\rm rd}{}^2/(2E)$, where $\sigma_{\rm rd}$ is a reference stress for the damage process.

Monkman-Grant parameter

Experimental relationship

$$C_{\rm MG} = (\dot{\varepsilon}_{\rm min}^{\rm c})^m t_{\rm rup} \approx {\rm constant.}$$

For the two models the Monkman-Grant parameter have the values $\left(m=1
ight)$

$$C_{\rm MG} = \dot{\varepsilon}_{\rm min}^{\rm c} t_{\rm rup} = \frac{1}{1+k+2r} \frac{t_{\rm d} h_{\rm c}}{t_{\rm c} h_{\rm d}} \left(\frac{\sigma}{\sigma_{\rm r}}\right)^{p-2r} \mod 1$$
$$C_{\rm MG} = \frac{t_{\rm d}}{t_{\rm c}} \mod 2.$$

Model 2 can be obtained by imposing the following constrains to the model 1:

$$p = 2r,$$
 $\frac{1}{1+k+2r}\frac{t_{\rm d}h_{\rm c}}{t_{\rm c}h_{\rm c}} = \text{constant}.$

FE analysis and results

The models are implemented in ANSYS using the USERMAT subroutine and the mesh consists of mainly 20 node hexahedral ANSYS SOLID186 elements & some 10 node tetrahedal SOLID187 elements. Prescribed displacement history at the end of the tube nozzle.

The computed lifetime is roughly 150 cycles. Ramp time 1 hour and hold time 200 hours. Internal pressure 14 MPa.

Concluding remarks

- Thermodynamically consistent model for high-temperature creep fatigue analyses has been developed.
- A specific model with Norton-Bailey type creep and Kachanov-Rabotnov type damage models are used.
- Two version of the damage evolution equations. One-version satisfies the Monkman-Grant hypothesis exactly.
- Materials parameters for the 7CrMoVTiB10-10 steel (T24) have been estimated in the temperature range 500-600 ^oC.
- Developed models have been implemented in the ANSYS FE-software by using the USERMAT subroutine.
